Q: Substring match from beginning or end of line and column? So I have a file of data that I need to extract a substring from using 2 indices, one from the beginning of the line, and another from the end of the line. I have been doing some research and have come up with a couple solutions, but I am wondering if there are better ways to do this. Method 1 Let's say I have a string: a I am looking to extract: a Using the python package regex, I have come up with the following regex which does this perfectly. `re.sub(" ", re.findall(" ", text))` If you look at the output, it also matches the start and end of the line with Method 2 Same case except I want to start from the end of the line. So I do this: `re.sub("(.*?)", text)` This works fine for all but the start of the line. How would I modify this so it matches the start of the line as well? Method 3 The third method is what I was originally using, it matched the text in the same way as method 1 but then removes the from the start and end of the line: `re.sub(' ', text)` Here is the output: a So it is removing the from the start and end of the line, but it's not removing them from the beginning and end of the line. I have used `re.sub("(.*?)", text)` but nothing seems to be removing them. The final output should be: A: This is the solution that I came up with: `re.sub(' ', text)`
